

- `public String toString() {}` - If we want to print the object itself it should have this method.

It is a string method defined in the `java.lang.Object` class that returns a string representation of the object. Since, every class in JAVA inherits from `Object`, all classes have this method, & many override it to provide meaningful, human-readable output about the object's state.

- `toString()` represents an object as a String, while `display()` is a user-defined method generally used to display object data.
